Abstract: *Polygonal hybrid systems are a subclass of planar hybrid automata which can be represented by piecewise constant differential inclusions (SPDIs). Using an important object of SPDIs' phase portrait, the* invariance kernels, *which can be computed non-iteratively, we present a breadth-first search algorithm for solving the reachability problem for SPDIs. Invariance kernels play an important role in the termination of the algorithm.*

1 Introduction

A *hybrid system* is a system where both continuous and discrete behaviors interact with each other. A typical example is given by a discrete program that interacts with (controls, monitor, supervises) a continuous physical environment. In the last decade many (un)decidability results for a variety of problems concerning classes of hybrid systems have been given [ACH+95, ABDM00, BT00], [DM98, GM99, KV00]. One of the main research areas in hybrid systems is reachability analysis. Most of the proved decidability results are based on the existence of a finite and computable partition of the state space into classes of states which are equivalent with respect to reachability. This is the case for timed automata [AD94], and classes of rectangular automata [HKPV95] and hybrid automata with linear vector fields [LPY99]. For some particular classes of two-dimensional dynamical systems a *geometrical* method, which relies on the analysis of topological properties of the plane, has been developed. This approach has been proposed in [MP93]. There, it is shown that the reachability problem for two-dimensional systems with piece-wise constant derivatives (PCDs) is decidable. This result has been extended in [CV96] for planar piece-wise Hamiltonian systems and in [ASY01] for polygonal hybrid systems, a class of nondeterministic systems that correspond to piecewise constant differential inclusions on the plane (SPDIs [Sch02]); see Fig. 1. In [AMP95] it has been shown that the reachability problem for PCDs is undecidable for dimensions higher than two.

Another important issue in the analysis of a (hybrid) dynamical system is the study

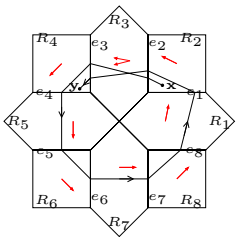

Figure 1: An SPDI and its trajectory segment.

of its qualitative behavior, namely the construction of its *phase portrait*. Some typical questions on this sense are "does every trajectory (except for the equilibrium point at the origin) converge to a limit cycle?", or "what is the biggest set such that any point on it is reachable from any other point on the set?". There have been very few results on the qualitative properties of trajectories of hybrid systems [ASY02, Aub01, DV95, KV96, KdB01, MS00, SJSL00]. In particular, the question of defining and constructing phase portraits of hybrid systems has not been directly addressed except in [MS00], where phase portraits of deterministic systems with piecewise constant derivatives are explored and in [ASY02] where viability and controllability kernels for polygonal differential inclusion systems have been computed.

In this report we show how an important object of phase portraits of SPDIs, the *invariance kernel,* can be used to compute SPDI reachability. This is an alternative algorithm to the one presented in [ASY01] for solving the reachability problem for SPDIs. This algorithm is a breadth-first search, in the spirit of traditional model checking algorithms, thus allowing for various standard model checking optimisation techniques to be applied to SPDI verification.

This technical report, together with the companion report [Sch03] in which the invariance kernel is defined and its properties derived, provide the technical background to [PS03].

Section 2 introduces the basic definitions required in the rest of the paper and section 3 defines the invariance kernel, stating a number of its properties. The SPDI verification algorithm presented in [ASY01] is informally discussed in section 4, and the new breadth-first search algorithm then presented in section 5. The correctness of the new algorithm is shown in section 6.

2 Preliminaries

2.1 Truncated affine multivalued functions

A (positive) *affine* function $f : \mathbb{R} \to \mathbb{R}$ is such that $f(x) = ax + b$ with $a > 0$. An *affine multivalued* function $F : \mathbb{R} \to 2^{\mathbb{R}}$, denoted $F = \langle f_l, f_u \rangle$, is defined by $F(x) = \langle f_l(x), f_u(x) \rangle$ where f_l and f_u are affine and $\langle \cdot, \cdot \rangle$ denotes an interval. For notational convenience, we do not make explicit whether intervals are open, closed, left-open or right-open, unless required for comprehension. For an interval $I = \langle l, u \rangle$ we have that $F(\langle l, u \rangle) = \langle f_l(l), f_u(u) \rangle$. The inverse of F is defined by $F^{-1}(x) = \{y \mid x \in F(y)\}$. It is not difficult to show that $F^{-1} = \langle f_u^{-1}, f_l^{-1} \rangle$. The *universal inverse* of F is defined by $\tilde{F}^{-1}(I) = I'$ iff I' is the greatest non-empty interval such that for all $x \in I'$, $F(x) \subseteq I$. Notice that if I is a singleton then $\tilde{F}^{-1}$ is defined only if $f_l = f_u$.

These classes of functions are closed under composition.

A *truncated affine multivalued* function (TAMF) $\mathcal{F} : \mathbb{R} \to 2^{\mathbb{R}}$ is defined by an affine multivalued function F and intervals $S \subseteq \mathbb{R}^+$ and $J \subseteq \mathbb{R}^+$ as follows: $\mathcal{F}(x) = F(x) \cap J$ if $x \in S$, otherwise $\mathcal{F}(x) = \emptyset$. For convenience we write $\mathcal{F}(x) = F(\{x\} \cap S) \cap J$. For an interval I, $\mathcal{F}(I) = F(I \cap S) \cap J$ and $\mathcal{F}^{-1}(I) = F^{-1}(I \cap J) \cap S$. We say that $\mathcal{F}$ is *normalized* if $S = \mathsf{Dom}\mathcal{F} = \{x \mid F(x) \cap J \neq \emptyset\}$ (thus, $S \subseteq F^{-1}(J)$) and $J = \mathsf{Im}\mathcal{F} = \mathcal{F}(S)$. In what follows we only consider normalized TAMFs. The *universal inverse* of $\mathcal{F}$ is defined by $\tilde{\mathcal{F}}^{-1}(I) = I'$ iff I' is the greatest non-empty interval such that for all $x \in I'$, $F(x) \subseteq I$ and $F(x) = \mathcal{F}(x)$.

TAMFs are closed under composition [ASY01]:

Theorem 1 The composition of two TAMFs $\mathcal{F}_1(I) = F_1(I \cap S_1) \cap J_1$ and $\mathcal{F}_2(I) = F_2(I \cap S_2) \cap J_2$, is the TAMF $(\mathcal{F}_2 \circ \mathcal{F}_1)(I) = \mathcal{F}(I) = F(I \cap S) \cap J$, where $F = F_2 \circ F_1$, $S = S_1 \cap F_1^{-1}(J_1 \cap S_2)$ and $J = J_2 \cap F_2(J_1 \cap S_2)$.

2.2 SPDI

An *angle* $\angle_{\mathbf{a}}^{\mathbf{b}}$ on the plane, defined by two non-zero vectors $\mathbf{a}, \mathbf{b}$ is the set of all positive linear combinations $\mathbf{x} = \alpha\ \mathbf{a} + \beta\ \mathbf{b}$, with $\alpha, \beta \geq 0$, and $\alpha + \beta > 0$. We can always assume that $\mathbf{b}$ is situated in the counter-clockwise direction from $\mathbf{a}$.

A *simple planar differential inclusion* (SPDI) is defined by giving a finite partition $\mathbb{P}$ of the plane into convex polygonal sets, and associating with each $P \in \mathbb{P}$ a couple of vectors $\mathbf{a}_P$ and $\mathbf{b}_P$. Let $\phi(P) = \angle_{\mathbf{a}_P}^{\mathbf{b}_P}$. The SPDI is $\dot{\mathbf{x}} \in \phi(P)$ for $\mathbf{x} \in P$.

Let $E(P)$ be the set of edges of P. We say that e is an *entry* of P if for all $\mathbf{x} \in e$ and

for all $\mathbf{c} \in \phi(P)$, $\mathbf{x} + \mathbf{c}\epsilon \in P$ for some $\epsilon > 0$. We say that e is an *exit* of P if the same condition holds for some $\epsilon < 0$. We denote by $In(P) \subseteq E(P)$ the set of all entries of P and by $Out(P) \subseteq E(P)$ the set of all exits of P.

Assumption 1 *All the edges in $E(P)$ are either entries or exits, that is, $E(P) = In(P) \cup Out(P)$.*

Example 1 Consider the SPDI illustrated in Fig. 1. For each region R_i, $1 \leq i \leq 8$, there is a pair of vectors $(\mathbf{a}_i, \mathbf{b}_i)$, where: $\mathbf{a}_1 = \mathbf{b}_1 = (1, 5)$, $\mathbf{a}_2 = \mathbf{b}_2 = (-1, \frac{1}{2})$, $\mathbf{a}_3 = (-1, \frac{11}{60})$ and $\mathbf{b}_3 = (-1, -\frac{1}{10})$, $\mathbf{a}_4 = \mathbf{b}_4 = (-1, -1)$, $\mathbf{a}_5 = \mathbf{b}_5 = (0, -1)$, $\mathbf{a}_6 = \mathbf{b}_6 = (1, -1)$, $\mathbf{a}_7 = \mathbf{b}_7 = (1, 0)$, $\mathbf{a}_8 = \mathbf{b}_8 = (1, 1)$. ■

A *trajectory segment* of an SPDI is a continuous function $\xi : [0, T] \to \mathbb{R}^2$ which is smooth everywhere except in a discrete set of points, and such that for all $t \in [0, T]$, if $\xi(t) \in P$ and $\dot{\xi}(t)$ is defined then $\dot{\xi}(t) \in \phi(P)$. The *signature*, denoted $\mathsf{Sig}(\xi)$, is the ordered sequence of edges traversed by the trajectory segment, that is, $e_1, e_2, \ldots$, where $\xi(t_i) \in e_i$ and $t_i < t_{i+1}$. If $T = \infty$, a trajectory segment is called a *trajectory*.

Assumption 2 *We will only consider trajectories with infinite signatures.*

2.3 Successors and predecessors

Given an SPDI, we fix a one-dimensional coordinate system on each edge to represent points laying on edges [ASY01]. For notational convenience, we will use e to denote both the edge and its one-dimensional representation. Accordingly, we write $\mathbf{x} \in e$ or $x \in e$, to mean "point $\mathbf{x}$ in edge e with coordinate x in the one-dimensional coordinate system of e". The same convention is applied to sets of points of e represented as intervals (e.g., $\mathbf{x} \in I$ or $x \in I$, where $I \subseteq e$) and to trajectories (e.g., "ξ starting in x" or "ξ starting in $\mathbf{x}$").

Now, let $P \in \mathbb{P}$, $e \in In(P)$ and $e' \in Out(P)$. For $I \subseteq e$, $\mathsf{Succ}_{e,e'}(I)$ is the set of all points in e' reachable from some point in I by a trajectory segment $\xi : [0, t] \to \mathbb{R}^2$ in P (i.e., $\xi(0) \in I \wedge \xi(t) \in e' \wedge \mathsf{Sig}(\xi) = ee'$). We have shown in [ASY01] that $\mathsf{Succ}_{e,e'}$ is a TAMF[1].

Example 2 Let $e_1, \ldots, e_8$ be as in Fig. 1 and $I = [l, u]$. We assume a one-dimensional coordinate system such that $e_i = S_i = J_i = (0, 1)$. We have that:

[1] In [ASY01] we explain how to choose the positive direction on every edge in order to guarantee positive coefficients in the TAMF.

$$F_{e_1e_2}(I) = \left[\frac{l}{2}, \frac{u}{2}\right] \qquad F_{e_2e_3}(I) = \left[l - \frac{1}{10}, u + \frac{11}{60}\right]$$
$$F_{e_ie_{i+1}}(I) = I \quad 3 \leq i \leq 7 \qquad F_{e_8e_1}(I) = \left[l + \frac{1}{5}, u + \frac{1}{5}\right]$$

with $\mathsf{Succ}_{e_ie_{i+1}}(I) = F_{e_ie_{i+1}}(I \cap S_i) \cap J_{i+1}$, for $1 \leq i \leq 7$, and $\mathsf{Succ}_{e_8e_1}(I) = F_{e_8e_1}(I \cap S_8) \cap J_1$. ■

Given a sequence $w = e_1, e_2, \ldots, e_n$, Theorem 1 implies that the successor of I along w defined as $\mathsf{Succ}_w(I) = \mathsf{Succ}_{e_{n-1},e_n} \circ \ldots \circ \mathsf{Succ}_{e_1,e_2}(I)$ is a TAMF.

Example 3 Let $\sigma = e_1 \cdots e_8e_1$. We have that $\mathsf{Succ}_\sigma(I) = F(I \cap S) \cap J$, where:

$$F(I) \;=\; \left[\frac{l}{2} + \frac{1}{10}, \frac{u}{2} + \frac{23}{60}\right]$$

$S = (0, 1)$ and $J = (\frac{1}{5}, \frac{53}{60})$ are computed using Theorem 1. ■

For $I \subseteq e'$, $\mathsf{Pre}_{e,e'}(I)$ is the set of points in e that can reach a point in I by a trajectory segment in P. We have that[ASY01]: $\mathsf{Pre}_{e,e'} = \mathsf{Succ}^{-1}_{e,e'}$ and $\mathsf{Pre}_\sigma = \mathsf{Succ}^{-1}_\sigma$.

Example 4 Let $\sigma = e_1 \ldots e_8e_1$ be as in Fig. 1 and $I = [l, u]$. We have that $\mathsf{Pre}_{e_ie_{i+1}}(I) = F^{-1}_{e_ie_{i+1}}(I \cap J_{i+1}) \cap S_i$, for $1 \leq i \leq 7$, and $\mathsf{Pre}_{e_8e_1}(I) = F^{-1}_{e_8e_1}(I \cap J_1) \cap S_8$, where:

$$F^{-1}_{e_1e_2}(I) = [2l, 2u] \qquad F^{-1}_{e_2e_3}(I) = \left[l - \frac{11}{60}, u + \frac{1}{10}\right]$$
$$F^{-1}_{e_ie_{i+1}}(I) = I \quad 3 \leq i \leq 7 \qquad F^{-1}_{e_8e_1}(I) = \left[l - \frac{1}{5}, u - \frac{1}{5}\right]$$

Besides, $\mathsf{Pre}_\sigma(I) = F^{-1}(I \cap J) \cap S$, where $F^{-1}(I) = [2l - \frac{23}{30}, 2u - \frac{1}{5}]$. ■

2.4 Qualitative analysis of simple edge-cycles

Let $\sigma = e_1 \cdots e_ke_1$ be a simple edge-cycle, i.e., $e_i \neq e_j$ for all $1 \leq i \neq j \leq k$. Let $\mathsf{Succ}_\sigma(I) = F(I \cap S) \cap J$ with $F = \langle f_l, f_u \rangle$ (we suppose that this representation is normalized). We denote by $\mathcal{D}_\sigma$ the one-dimensional discrete-time dynamical system defined by Succ_σ, that is $x_{n+1} \in \mathsf{Succ}_\sigma(x_n)$.

Assumption 3 *None of the two functions f_l, f_u is the identity.*

Let l^* and u^* be the fixpoints[2] of f_l and f_u, respectively, and $S \cap J = \langle L, U \rangle$. We have shown in [ASY01] that a simple cycle is of one of the following types:

STAY. The cycle is not abandoned neither by the leftmost nor the rightmost trajectory, that is, $L \leq l^* \leq u^* \leq U$.

[2]Obviously, the fixpoint x^* is computed by solving a linear equation $f(x^*) = x^*$.

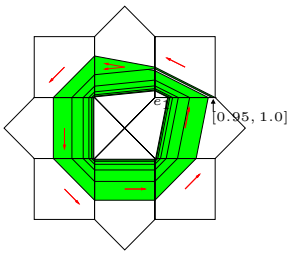

Figure 2: Reachability analysis.

DIE. The rightmost trajectory exits the cycle through the left (consequently the leftmost one also exits) or the leftmost trajectory exits the cycle through the right (consequently the rightmost one also exits), that is, $u^* < L \vee l^* > U$.

EXIT-BOTH. The leftmost trajectory exits the cycle through the left and the rightmost one through the right, that is, $l^* < L \wedge u^* > U$.

EXIT-LEFT. The leftmost trajectory exits the cycle (through the left) but the rightmost one stays inside, that is, $l^* < L \leq u^* \leq U$.

EXIT-RIGHT. The rightmost trajectory exits the cycle (through the right) but the leftmost one stays inside, that is, $L \leq l^* \leq U < u^*$.

Example 5 Let $\sigma = e_1 \cdots e_8 e_1$. We have that $S \cap J = \langle L, U \rangle = (\frac{1}{5}, \frac{53}{60})$. The fixpoints of the equation in example 3 are such that $L = l^* = \frac{1}{5} < u^* = \frac{23}{30} < U$. Thus, σ is STAY. ■

The classification above gives us some information about the qualitative behavior of trajectories. Any trajectory that enters a cycle of type DIE will eventually quit it after a finite number of turns. If the cycle is of type STAY, all trajectories that happen to enter it will keep turning inside it forever. In all other cases, some trajectories will turn for a while and then exit, and others will continue turning forever. This information is very useful for solving the reachability problem [ASY01].

Example 6 Consider again the cycle $\sigma = e_1 \cdots e_8 e_1$. Fig. 2 shows the reach set of the interval $[0.95, 1.0] \subset e_1$. Notice that the leftmost trajectory "converges to" the limit $l^* = \frac{1}{5}$. Fig. 2 has been automatically generated by the SPeeDI toolbox [APSY02] we have developed for reachability analysis of SPDIs. ■

The above result does not allow us to directly answer other questions about the behavior of the SPDI such as determine for a given point (or set of points) whether

any trajectory (if it exists) starting in the point remains in the cycle forever. In order to do this, we need to further study the properties of the system around simple edge-cycles and in particular STAY cycles. See the appendix for some important properties of STAY cycles.

3 Invariance Kernel

In this section we define the notion of *invariance kernel* and we show how to compute it. In general, an *invariant set* is a set of points such that for any point in the set, every trajectory starting in such point remains in the set forever and the *invariance kernel* is the largest of such sets. Proofs of these results can be found in [Sch03].

In particular, for SPDI, given a cyclic signature, an *invariant set* is a set of points which keep rotating in the cycle forever and the *invariance kernel* is the largest of such sets. We show that this kernel is a non-convex polygon (often with a hole in the middle) and we give a non-iterative algorithm for computing the coordinates of its vertices and edges.

In what follows, let $K \subset \mathbb{R}^2$. We recall the definition of *viable* trajectory. A trajectory ξ is *viable* in K if $\xi(t) \in K$ for all $t \geq 0$. K is a *viability domain* if for every $\mathbf{x} \in K$, there exists at least one trajectory ξ, with $\xi(0) = \mathbf{x}$, which is viable in K.

Definition 1 *We say that a set K is* invariant *if for any $x \in K$ such that there exists at least one trajectory starting in it, every trajectory starting in x is viable in K. Given a set K, its largest invariant subset is called the* invariance kernel *of K and is denoted by $\mathsf{Inv}(K_\sigma)$.* ■

We denote by $\mathcal{D}_\sigma$ the one-dimensional discrete-time dynamical system defined by Succ_σ, that is $x_{n+1} \in \mathsf{Succ}_\sigma(x_n)$. The concepts above can be defined for $\mathcal{D}_\sigma$, by setting that a trajectory $x_0 x_1 \ldots$ of $\mathcal{D}_\sigma$ is viable in an interval $I \subseteq \mathbb{R}$, if $x_i \in I$ for all $i \geq 0$. Similarly we say that an interval I in an edge e is invariant if *any* trajectory starting on $x_0 \in I$ is viable in I.

Before showing how to compute the invariance kernel of a cycle, we give a characterization of one-dimensional discrete-time invariant.

Lemma 1 *For $\mathcal{D}_\sigma$ and σ a STAY cycle, the following is valid. If I is such that $F(I) \subseteq I$ and $F(I) = \mathcal{F}(I)$ then I is invariant. On the other hand if I is invariant then $F(I) = \mathcal{F}(I)$.*

Theorem 2 *For $\mathcal{D}_\sigma$, if σ is STAY then* $\mathsf{Inv}(e_1) = \widetilde{\mathsf{Pre}}(J)$, *otherwise* $\mathsf{Inv}(e_1) = \emptyset$.

The proof of these results can be found in [Sch03] and [PS03].

The invariance kernel for the continuous-time system can be now found by propagating $\widetilde{\mathsf{Pre}}(J)$ from e_1 using the following operator. The *extended $\forall$-predecessor* of an output edge e of a region R is the set of points in R such that every trajectory segment starting in such point reaches e without traversing any other edge. More formally,

Definition 2 *Let R be a region and e be an edge in $Out(R)$. The* e-extended $\forall$-predecessor *of I, $\widetilde{\overline{\mathsf{Pre}}}_e(I)$ is defined as:*

$$\widetilde{\overline{\mathsf{Pre}}}_e(I) = \{\mathbf{x} \mid \forall \xi : [0,t] \to \mathbb{R}^2, t > 0 \;.\; \xi(0) = \mathbf{x} \wedge \xi(t) \in I \wedge \mathsf{Sig}(\xi) = e\}$$

■

The above notion can be extended to cyclic signatures (and so to edge-signatures) as follows. Let $\sigma = e_1, \ldots, e_k$ be a cyclic signature. For $I \subseteq e_1$, the *σ-extended $\forall$-predecessor* of I, $\widetilde{\overline{\mathsf{Pre}}}_\sigma(I)$ is the set of all $\mathbf{x} \in \mathbb{R}^2$ for which any trajectory segment ξ starting in $\mathbf{x}$, reaches some point in I, such that $\mathsf{Sig}(\xi)$ is a suffix of $e_2 \ldots e_k e_1$.

It is easy to see that $\widetilde{\overline{\mathsf{Pre}}}_\sigma(I)$ is a polygonal subset of the plane which can be calculated using the following procedure. First compute $\widetilde{\overline{\mathsf{Pre}}}_{e_i}(I)$ for all $1 \leq i \leq n$ and then apply this operation k times: $\widetilde{\overline{\mathsf{Pre}}}_\sigma(I) = \bigcup_{i=1}^{k} \widetilde{\overline{\mathsf{Pre}}}_{e_i}(I_i)$, with $I_1 = I$, $I_k = \widetilde{\mathsf{Pre}}_{e_k e_1}(I_1)$ and $I_i = \widetilde{\mathsf{Pre}}_{e_i e_{i+1}}(I_{i+1})$, for $2 \leq i \leq k-1$.

Now, let define the following set:

$$K_\sigma = \bigcup_{i=1}^{k} (\mathtt{int}(P_i) \cup e_i)$$

where P_i is such that $e_{i-1} \in In(P_i)$, $e_i \in Out(P_i)$ and $\mathtt{int}(P_i)$ is the interior of P_i.

We can now compute the invariance kernel of K_σ.

Theorem 3 *If σ is STAY then* $\mathsf{Inv}(K_\sigma) = \widetilde{\overline{\mathsf{Pre}}}_\sigma(\widetilde{\mathsf{Pre}}_\sigma(J))$, *otherwise* $\mathsf{Inv}(K_\sigma) = \emptyset$.

Proof: Trivially $\mathsf{Inv}(K_\sigma) = \emptyset$ for any type of cycle but STAY. That $\mathsf{Inv}(K_\sigma) = \widetilde{\overline{\mathsf{Pre}}}_\sigma(\widetilde{\mathsf{Pre}}_\sigma(J))$ for STAY cycles, follows directly from Theorem 2 and definition of $\widetilde{\overline{\mathsf{Pre}}}$. □

Example 7 Let $\sigma = e_1 \ldots e_8 e_1$. Fig. 3 depicts: (a) K_σ, and (b) $\widetilde{\overline{\mathsf{Pre}}}_\sigma(\widetilde{\mathsf{Pre}}_\sigma(J))$ ■

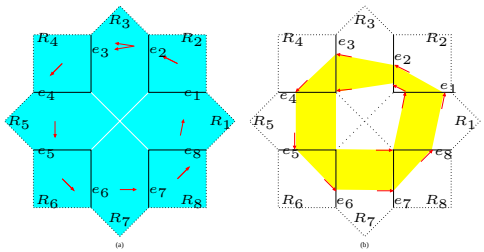

Figure 3: Invariance kernel.

4 The Previous Depth-First Search Algorithm

The decidability proof of [ASY01] already provides an algorithmic way of deciding reachability in SPDIs, which was implemented in our tool SPeeDI [APSY02]. We will give an overview of the algorithm to be able to compare and contrast it with the new algorithm that we are proposing. The decidability proof is split into three steps:

1. Identify a notion of *types of signatures,* each of which 'embodies' a number of signatures through the SPDI.
2. Prove that a finite number of types suffice to cover all edge signatures. Furthermore, given an SPDI, this set is computable.
3. Give an algorithm which decides whether a given type includes a signature which is feasible under the differential inclusion constraints of the SPDI.

We will not go into the details (see [ASY01] for more details), but will outline a number of items which will allow us to compare the algorithms.

Definition 3 *A* type signature *is a sequence of edge signatures with alternating loops:* $r_1 s_1^+ r_2 s_2^+ \dots s_n^+ r_{n+1} s^*$. *The* r_i *parts of the type signature are called the* sequential paths *while the* s_i *parts called* iteration paths. *The last iteration path* s *is always a STAY loop. The interpretation of a type is similar to that of regular expressions:*

$$\mathit{signatures}(r_1 s_1^+ r_2 s_2^+ \dots s_n^+ r_{n+1} s^*) \stackrel{\text{df}}{=} \{r_1 s_1^{k_1} r_2 s_2^{k_2} \dots s_n^{k_n} r_{n+1} s^k \mid k_i > 0,\ k \geq 0\}$$

In [ASY01], one can find details of how to decide whether a given type signature includes an edge signature which is feasible. Clearly, given a source edge e_0 and a destination edge e_f, there potentially exists an infinite number of type signatures from e_0 to e_f. To reduce this to a finite number, [ASY01] applies a number of syntactic

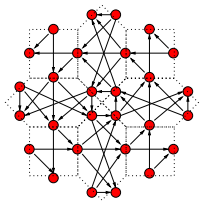

Figure 4: The edge-graph of the swimmer SPDI example

constraints which ensure finiteness, but do not leave out any possibly feasible edge signatures. Using these constraints it is easy to implement a depth-first traversal of the SPDI to check all possible type signatures. Note that a breath-first traversal would require excessive storage requirements of all intermediate nodes.

From our experience in using SPeeDI, our implementation of this algorithm, the main deficiency of this approach is that incorrect systems which may have 'short' counter-examples (in terms of type signature length) end up lost in the exploration of long paths — ending up either taking an excessive amount of time to find the counter-example, or coming up with a long counter-example difficult to use for debugging the hybrid system. Ideally, we should be able to find a shortest counter-example without the need of exhaustive exploration of the SPDI.

5 A New Breadth-First Algorithm

As is evident from the previous section, it is desirable to have a breadth-first algorithm to be able to identify shortest[3] counter-examples and be able to use standard algorithms for optimisation.

Definition 4 *The* edge graph *of an SPDI with partition* $\mathbb{P}$ *is the graph with the region edges as nodes:* $N = \cup_{P \in \mathbb{P}} E(P)$*; and transitions between two edges in the same partition with the first being an input and second an output edge:* $T = \{(e, e') \mid \exists P \in \mathbb{P} \,.\, e, e' \in P,\ e \in In(P),\ e' \in Out(P)\}$.

Example 8 *To illustrate the notion of an edge-graph, Fig. 4 illustrates the edge-graph corresponding to the SPDI representing the swimmer example given in Fig. 1.*

[3]Note that shortest, in this context, is not in terms or length of path on the SPDI, or number of edges visited, but on the length of the abstract signature which includes a counter-example.

Definition 5 *The* meta-graph *of an SPDI S is its edge graph augmented with the loops in the SPDI:*

1. *An unlabelled transition for every transition in the original graph:*
   $\{e \to e' \mid$ *input edge e and output edge e' belong to the same region* $\}$
2. *A set of labelled transitions, one for each simple loop in the original graph which is eventually left:* $\{e \overset{se}{\looparrowright} e' \mid \mathsf{head}(s) \neq e',\ esee' \text{ is a valid path in } S\}$
3. *A set of labelled sink edges, one for each simple loop of type STAY which is never left:* $\{e \overset{se}{\circlearrowleft} \mid ese \text{ is a valid path in } S,\ se \text{ is a STAY loop}\}$

Note that reachability along a path through the meta-graph corresponds to that of a type signature as defined in the previous section. For example $e_1 \to e_2 \overset{s_1}{\looparrowright} e_3 \overset{s_2}{\circlearrowleft}$ would correspond to $e_1 e_2 s_1^+ e_3 s_2^*$. From the result in [ASY01], which states that only a finite number of abstract signatures (of finite length) suffices to describe the set of all signatures through the graph, it immediately follows that for any SPDI, it suffices to explore the meta-graph to a finite depth to deduce the reachable set.

Proposition 1 *Given an SPDI S, reachability in S is equivalent to reachability in the meta-graph of S.*

To implement the meta-graph traversal, we will define the functions corresponding to the different transitions which, given a set of edge-intervals already visited, return a new set of edge-intervals which will be visited along that transition:

$$\begin{aligned}
\to(E) &\overset{df}{=} \{\mathsf{Succ}_{e,e'}(i) \mid i \in E,\ i \subseteq e,\ e \to e'\} \\
\looparrowright(E) &\overset{df}{=} \{\mathsf{Succ}_p(i) \mid i \in E,\ i \subseteq e,\ e \overset{l}{\looparrowright} e',\ p \text{ prefix } el^+e'\} \\
\circlearrowleft(E) &\overset{df}{=} \{\mathsf{Succ}_p(i) \cap \mathsf{Inv}(l) \mid i \in E,\ i \subseteq e,\ e \overset{l}{\circlearrowleft},\ p \text{ prefix } el^*\}
\end{aligned}$$

Note that, using the techniques developed in [ASY01], we can always calculate the first two of the above. Furthermore, we are guaranteed that if E consists of a finite number of edge-intervals, so will $\to(E)$ and $\looparrowright(E)$. Unfortunately, this is not the case with $\circlearrowleft(E)$. However, it is possible to compute whether a given set of edge-intervals and $\circlearrowleft(E)$ (E being a finite set of edge-intervals) overlap.

If we consider the standard model checking approach, we can use a given SPDI with transitions $\to$, meta-transitions $\looparrowright$, sink-transitions $\circlearrowleft$ and initial set I:

$$R_0 \overset{df}{=} I \qquad\qquad R_{n+1} \overset{df}{=} R_n \cup \to(R_n) \cup \looparrowright(R_n) \cup \circlearrowleft(R_n)$$

We can terminate once nothing else is added: $R_{N+1} = R_N$. Edge-interval sets R_n can be represented enumeratively. However, as already noted, STAY loops represented

by sinks may induce an infinite number of disjoint intervals. However, since sinks are dead end transitions, we can simplify the reachability analysis by performing the sinks only at the end:

$$R_{n+1} \stackrel{df}{=} R_n \cup \rightarrow (R_n) \cup \not\rightarrow (R_n)$$

Since the termination condition depended on the fact that we were also applying the sink transitions $\circlearrowleft$, we add this when we check the termination condition: $R_N \cup \circlearrowleft (R_N) = R_{N+1} \cup \circlearrowleft (R_{N+1})$. Although the problem has been simply moved to the termination test, we show that this condition can be reduced to the simpler, and testable: $R_{N+1} \setminus R_N \subseteq \mathsf{Inv}$, where Inv is the set of all invariance kernels $\bigcup_{l \in STAY} \mathsf{Inv}(l)$. The proofs can be found in a related technical report.[4]

We can now implement the algorithm in a similar manner as standard forward model checking:

```
preR := {}; R := Src;
while (R \ preR ⊈ Inv)
    preR := R; R := R∪ → (R)∪ ↛ (R);
    if (Dst overlaps R) then return REACHABLE;
if (Dst overlaps (R ∪ ↺ (R)))then return REACHABLE else return UNREACHABLE;
```

6 Algorithm Correctness

We will now prove a number of properties to ascertain the correctness of the algorithm. As noted in the paper, we have the algorithm derived directly from the BFS search of the meta-graph of the SPDI, and the implementation which uses a different condition (which we know how to compute) to check for termination.

In both cases, the reachability analysis of an SPDI with meta-graph $\langle E, \rightarrow, \not\rightarrow, \circlearrowleft \rangle$ starting from a set of edge-intervals I proceeds by calculating a sequence of (finite) sets of edge-intervals which are reachable:

$$\begin{aligned} R_0 &\stackrel{df}{=} I \\ R_{n+1} &\stackrel{df}{=} R_n \cup \rightarrow (R_n) \cup \not\rightarrow (R_n) \end{aligned}$$

Since the exploration corresponds to a BFS search through signatures in the graph of the SPDI, we terminate when, after applying the STAY cycles, we have added nothing new to the reachable set:

[4] Reviewers may find the proofs in the appendix.

$$\text{Smallest } N \text{ such that: } R_N \cup \circlearrowleft (R_N) = R_{N+1} \cup \circlearrowleft (R_{N+1})$$

We call the set of reachable intervals R: $R \stackrel{df}{=} R_N$.

We have proposed that an alternative termination condition to use is:

$$\text{Smallest } M \text{ such that: } R_{M+1} \setminus R_M \subseteq \mathsf{Inv}$$

We call the set of intervals calculated with this alternative termination condition R': $R' \stackrel{df}{=} R_M$.

Proposition 2 *The transition operators obey a number of basic laws:*

(a) Distributivity:

$$\begin{aligned} \rightarrow (A \cup B) &= \rightarrow (A) \cup \rightarrow (B) \\ \not\rightarrow (A \cup B) &= \not\rightarrow (A) \cup \not\rightarrow (B) \\ \circlearrowleft (A \cup B) &= \circlearrowleft (A) \cup \circlearrowleft (B) \end{aligned}$$

(b) Absorption:

$$\begin{aligned} \rightarrow (\circlearrowleft (A)) &\subseteq \circlearrowleft (A) \\ \not\rightarrow (\circlearrowleft (A)) &\subseteq \circlearrowleft (A) \\ \circlearrowleft (\circlearrowleft (A)) &= \circlearrowleft (A) \end{aligned}$$

(c) Invariance kernel:

$$\begin{aligned} \circlearrowleft (A) &\subseteq \mathsf{Inv} \\ \rightarrow (R_n) \cap \mathsf{Inv} &\subseteq \circlearrowleft (R_{n+1}) \\ \not\rightarrow (R_n)) \cap \mathsf{Inv} &\subseteq \circlearrowleft (R_{n+1}) \end{aligned}$$

Note that from the distributivity laws, it follows that all transition functions are monotonic eg $A \subseteq B \Rightarrow \rightarrow (A) \subseteq \rightarrow (B)$.

Lemma 2 *The sequence of R_n is an increasing sequence:*

(a) $R_n \subseteq R_{n+1}$

(b) $R_n \cup \circlearrowleft (R_n) \subseteq R_{n+1} \cup \circlearrowleft (R_{n+1})$

Proof: Follows directly from the definition of R_{n+1} and monotonicity of $\circlearrowleft$. □

Lemma 3 *Once the first termination condition is satisfied by R_n, it continues to be satisfied by all subsequent R_m, $m \geq n$.*

$$R_n \cup \circlearrowleft (R_n) = R_{n+1} \cup \circlearrowleft (R_{n+1}) \Rightarrow \forall m \geq n \cdot R_n \cup \circlearrowleft (R_n) = R_m \cup \circlearrowleft (R_m)$$

Proof: It suffices to show that the property holds for one step:

$$R_n \cup \circlearrowleft (R_n) = R_{n+1} \cup \circlearrowleft (R_{n+1}) \Rightarrow R_{n+1} \cup \circlearrowleft (R_{n+1}) = R_{n+2} \cup \circlearrowleft (R_{n+2})$$

The lemma then follows by induction.

$$\begin{array}{ll} & R_{n+1} \cup \circlearrowleft (R_{n+1}) = R_n \cup \circlearrowleft (R_n) \\ \Rightarrow & \{ \text{ basic set theory } \} \\ & R_{n+1} \subseteq R_n \cup \circlearrowleft (R_n) \\ \Rightarrow & \{ \text{ definition of } R_{n+2} \} \\ & R_{n+2} \subseteq (R_n \cup \circlearrowleft (R_n)) \cup \\ & \quad \rightarrow (R_n \cup \circlearrowleft (R_n)) \cup \\ & \quad \nrightarrow (R_n \cup \circlearrowleft (R_n)) \\ \Rightarrow & \{ \text{ distributivity of } \rightarrow \text{ and } \nrightarrow \text{ – proposition 2 } \} \\ & R_{n+2} \subseteq (R_n \cup \rightarrow (R_n) \cup \nrightarrow (R_n)) \cup \\ & \quad (\circlearrowleft (R_n) \cup \rightarrow (\circlearrowleft (R_n)) \cup \nrightarrow (\circlearrowleft (R_n)) \\ \Rightarrow & \{ \text{ definition of } R_{n+1} \} \\ & R_{n+2} \subseteq R_{n+1} \cup (\circlearrowleft (R_n) \cup \rightarrow (\circlearrowleft (R_n)) \cup \nrightarrow (\circlearrowleft (R_n)) \\ \Rightarrow & \{ \text{ absorbtion laws from proposition 2 } \} \\ & R_{n+2} \subseteq R_{n+1} \cup \circlearrowleft (R_n) \\ \Rightarrow & \{ \text{ lemma 2 and monotonicity of } \circlearrowleft \} \\ & R_{n+2} \subseteq R_{n+1} \cup \circlearrowleft (R_{n+1}) \\ \Rightarrow & \{ \text{ monotonicity of } \circlearrowleft \text{ and absorbtion laws from proposition 2 } \} \\ & R_{n+2} \cup \circlearrowleft (R_{n+2}) \subseteq R_{n+1} \cup \circlearrowleft (R_{n+1}) \\ \Rightarrow & \{ \text{ lemma 2 } \} \\ & R_{n+2} \cup \circlearrowleft (R_{n+2}) = R_{n+1} \cup \circlearrowleft (R_{n+1}) \end{array}$$

□

Corollary 1 *If $R_n \cup \circlearrowleft (R_n) = R_{n+1} \cup \circlearrowleft (R_{n+1})$, then $R_n \cup \circlearrowleft (R_n) = R$.*

Lemma 4 *A similar result to the previous lemma:*

$$R_{n+1} \setminus R_n \subseteq \circlearrowleft (R_{n+1}) \Rightarrow R_{n+2} \setminus R_{n+1} \subseteq \circlearrowleft (R_{n+1})$$

Proof: The proof follows from the previous results and definition of R_n:

$$
\begin{array}{ll}
 & R_{n+1} \setminus R_n \subseteq \circlearrowleft (R_{n+1}) \\
\Rightarrow & \{ \text{ basic set theory } \} \\
 & R_{n+1} \subseteq R_n \cup \circlearrowleft (R_{n+1}) \\
\Rightarrow & \{ \text{ by definition of } R_{n+2} \} \\
 & R_{n+2} \subseteq (R_n \cup \circlearrowleft (R_{n+1})) \cup \rightarrow (R_n \cup \circlearrowleft (R_{n+1})) \cup \nrightarrow (R_n \cup \circlearrowleft (R_{n+1})) \\
\Rightarrow & \{ \text{ distributivity of } \rightarrow \text{ and } \nrightarrow \text{ – proposition 2 } \} \\
 & R_{n+2} \subseteq (R_n \cup \rightarrow (R_n) \cup \nrightarrow (R_n)) \cup \\
 & \qquad (\circlearrowleft (R_{n+1}) \cup \rightarrow (\circlearrowleft (R_{n+1})) \cup \nrightarrow (\circlearrowleft (R_{n+1}))) \\
\Rightarrow & \{ \text{ definition of } R_{n+1} \} \\
 & R_{n+2} \subseteq R_{n+1} \cup (\circlearrowleft (R_{n+1}) \cup \rightarrow (\circlearrowleft (R_{n+1})) \cup \nrightarrow (\circlearrowleft (R_{n+1}))) \\
\Rightarrow & \{ \text{ proposition 2 } \} \\
 & R_{n+2} \subseteq R_{n+1} \cup \circlearrowleft (R_{n+1}) \\
\Rightarrow & \{ \text{ basic set theory } \} \\
 & R_{n+2} \setminus R_{n+1} \subseteq \circlearrowleft (R_{n+1})
\end{array}
$$

□

Theorem 4 *The second termination condition guarantees termination. In other words, M is well-defined.*

Proof: From [ASY01], it follows that N is well-defined, or (in other words) that the first termination condition is eventually satisfied. We will now show that N also satisfies the second termination condition, and hence M is well-defined.

$$
\begin{array}{ll}
 & R_N \cup \circlearrowleft (R_N) = R_{N+1} \cup \circlearrowleft (R_{N+1}) \\
\Rightarrow & R_{N+1} \cup \circlearrowleft (R_{N+1}) \subseteq R_N \cup \circlearrowleft (R_N) \\
\Rightarrow & \{ \text{ basic set theory } \} \\
 & R_{N+1} \cup \circlearrowleft (R_{N+1}) \cup \mathsf{Inv} \subseteq R_N \cup \circlearrowleft (R_N) \cup \mathsf{Inv} \\
\Rightarrow & \{ \text{ by properties related to } \mathsf{Inv} \text{ in proposition 2 } \} \\
 & R_{N+1} \cup \mathsf{Inv} \subseteq R_N \cup \mathsf{Inv} \\
\Rightarrow & \{ \text{ basic set theory } \} \\
 & R_{N+1} \setminus R_N \subseteq \mathsf{Inv}
\end{array}
$$

□

Theorem 5 *Both termination conditions give the same result: $R = R'$.*

Proof: We start by showing that whenever the second termination condition is satisfied, the first condition is satisfied one step later, which then allows us to conclude that S and R are identical:

$$
\begin{array}{ll}
 & R_{M+1} \setminus R_M \subseteq \mathsf{Inv} \\
\Rightarrow & \{ \text{ basic set theory } \} \\
 & R_{M+1} \setminus R_M = (R_{M+1} \setminus R_M) \cap \mathsf{Inv} \\
\Rightarrow & \{ \text{ definition of } R_{M+1} \} \\
 & R_{M+1} \setminus R_M \subseteq (\rightarrow (R_M) \cup \nrightarrow (R_M)) \cap \mathsf{Inv} \\
\Rightarrow & \{ \text{ proposition 2 } \} \\
 & R_{M+1} \setminus R_M \subseteq \circlearrowleft (R_{M+1}) \\
\Rightarrow & \{ \text{ lemma 4 } \} \\
 & R_{M+2} \setminus R_{M+1} \subseteq \circlearrowleft (R_{M+1}) \\
\Rightarrow & \{ \text{ basic set theory } \} \\
 & R_{M+2} \subseteq R_{M+1} \cup \circlearrowleft (R_{M+1}) \\
\Rightarrow & \{ \text{ absorbtion laws from proposition 2 } \} \\
 & R_{M+2} \cup \circlearrowleft (R_{M+2} \subseteq R_{M+1} \cup \circlearrowleft (R_{M+1}) \\
\Rightarrow & \{ \text{ lemma 2 } \} \\
 & R_{M+1} \cup \circlearrowleft (R_{M+1}) = R_{M+2} \cup \circlearrowleft (R_{M+2}) \\
\Rightarrow & \{ \text{ corollary 1 } \} \\
 & R_{M+1} \cup \circlearrowleft (R_{M+1}) = R \\
\Rightarrow & \{ \text{ definition of } R' \} \\
 & R' = R
\end{array}
$$

□

7 Conclusion

One of the contributions of this paper is an automatic procedure to obtain an important object of the phase portrait of simple planar differential inclusions (SPDIs [Sch02]), namely invariance kernels.

We have also presented a breadth-first search algorithm for solving the reachability problem for SPDIs. The advantage of such an algorithm is that it is much simpler than the one presented in [ASY01] and it reminds the classical model checking algorithm for computing reachability. Invariance kernels play a crucial role to prove termination of the BFS reachability algorithm.

We intend to implement the algorithm in order to compare it with the previous algorithm for SPDIs [APSY02].

Acknowledgments. We are thankful to Eugene Asarin and Sergio Yovine for the valuable discussions.
